Nevertheless, it is necessary to understand the medical physiology behind the regulation of calcium levels before one can proceed to its abnormal values. Today, we are going to cover up Normal physiology of the calcium as an medical entity, how the Parathyroid hormone (PTH) from parathyroid gland clashes with Calcitonin from the thyroid gland.

An adult human body contains 1,000 g of calcium. 1 About 99% of this is in the form of hydroxyapatite salt (provides structural rigidity along with collagen matrix), and the remainder (1%) is in the extracellular fluids and regulates various biochemical events. In the blood, calcium exists in ionized (50%), protein-bound (40% to plasma proteins), and complexed (10% to citrate and phosphate) forms.

Assay Of Calcium-regulating Hormones eBook

Three major hormones (PTH, vitamin D, and calcitonin) interact to maintain a constant concentration of calcium, despite variations in intake and excretion. Other hormones, such as adrenal corticosteroids, estrogens, thyroxine, somatotropin, and glucagon , may also contribute to the maintenance of calcium homeostasis.

In health, various hormones keep the blood calcium levels within a narrow range, but changes in the level of these hormones or, rarely, reduced consumption of calcium in the diet can lead to the calcium level dropping too low. Calcium is found in many foods especially dairy products and milk, and most diets contain sufficient quantities of calcium.

Control of Calcium Homeostasis. The extracellular fluid (or plasma) calcium concentration is tightly controlled by a complex homeostatic mechanism involving

fluxes of calcium between the extracellular fluid (ECF) and the kidney, bone, and gut. These fluxes are carefully regulated by three major hormones: parathyroid hormone (PTH), calcitonin, and 1,25-dihydroxyvitamin D [$1,25(\text{OH})_2\text{D}_3$].

Although the calcium circulating in your blood comprises less than 1 percent of your total body calcium, maintaining appropriate levels is vital for bone health and normal muscle and nerve function. Three principal hormones regulate blood calcium levels: parathyroid hormone, vitamin D and calcitonin.

It involves an interplay between the actions of two polypeptide hormones, parathyroid hormone (PTH) and calcitonin (CT), and a sterol hormone, $1,25$ -dihydroxyvitamin D [$1,25$ - $(\text{OH})_2\text{D}_3$]. The regulation of the biosynthesis and the secretion of the polypeptide hormones is accomplished by a negative feedback mechanism involving the calcium ion activity of the extracellular fluids (Figure 2).

Calcium metabolism is the movement and regulation of calcium ions (Ca^{2+}) in (via the gut) and out (via the gut and kidneys) of the body, and between body compartments: the blood plasma, the extracellular and intracellular fluids, and bone. Bone acts as a calcium storage center for deposits and withdrawals as needed by the blood via continual bone remodeling.
